Q: In C++, how to properly allocate the memory for a structure when the objects of that type exist in multiple threads? Say we have this class: `class MyClass{ public: MyClass(){ std::vector temp; //... } ~MyClass(){ } };` And we have two threads, both of which allocate objects of type `MyClass`: `int main(){ MyClass * a = new MyClass; MyClass * b = new MyClass; std::thread t1(myfunction,a); std::thread t2(myfunction,b); t1.join(); t2.join(); delete a; delete b; }` If thread `t1` ends first, then thread `t2` will allocate an object of type `MyClass`, but if it ends second, then thread `t1` will not have any objects to deallocate. What is the best way to address this issue? A: First, you should use a smart pointer or handle (like `shared_ptr`, `unique_ptr`, `auto_ptr`) instead of raw pointers. Next, the vector should be initialized in the constructor. In your example, it's just not very thread-safe and certainly will not work correctly if the threads are never joined. `class MyClass{ public: MyClass(size_t size) : vec(size) {} ~MyClass(){ } private: std::vector vec; };` Q: Get datetime in specific format I have a datetime like "2013-12-01T15:50:00.000Z" I need to get that in a specified format. Here is what I am doing, `DateTime dt = DateTime.ParseExact(this.logdate, "yyyy-MM-ddTHH:mm:ss.000Z", System.Globalization.CultureInfo.InvariantCulture);` But, it always returns me like "01.12.2013 15:50:00"
