A: When you are using `std::ifstream >>` instead of `std::istream >>`, you're using streaming input: the stream does not get the last character that's read from it until it's closed. Another approach is to read the whole buffer first and then analyze each character.

Q: Efficient way to find an item in a many-to-many relationship I have a many to many relationship like the following: `class ApplicationDto { Application application; List revisions; } class CommitDto { string branch; ... }` The "application" relationship is a collection of the "revision" relationship. A commit has multiple branches and a branch can be under multiple applications. What is the most efficient way for retrieving a given revision by application and branch? I am using Hibernate and I have various suggestions for mapping that may work.

A: To me, it seems like you are using either a bidirectional collection or an unidirectional relationship. In the first case, you need a m:n bidirectional relationship between Application and Commit. If you are using a separate collection for commits, then it could be a m:n unidirectional relationship as well. The application will store the commit and commit will store the application. Here is an example of the java mappings: `application.addToCommits(commit); commit.addToApplication(application);` See if that helps.

Parasitic infection is one of the most common causes of morbidity and mortality worldwide and one of the key factors in the continuing mortality attributable to malaria in sub-Saharan Africa. Although transmission in most areas of the world is associated with infection by a single species, Africa and the Americas have, in recent years, experienced a dramatic shift in malaria epidemiology with the emergence of two species, Plasmodium vivax and Plasmodium falciparum, that occur in sympatry. Both of these species can induce severe morbidity and can be transmitted by vectors that are also competent to transmit P. falciparum. However, the distribution of the two species within sympatry and between these habitats is not well characterized at the microscale. The current trend in vector control has been to target a single species. While this has been proven successful in `d0c515b9f4`

Sperms with and without the dye Eosin Y-0.5% were exposed to two concentrations of laser light (2 and 4 mW/cm2) for 1 s to induce photodamage; thereafter, the sperms were fertilized in vitro by the usual techniques. The in vivo fertility was evaluated by the total number of implantations obtained. The results show that the diploid survival of sperms with and without the dye is similar, although the duration of the survival is reduced in those spermatozoa with the dye. However, there is a significant decrease in the number of sperms able to reach the implantation site after photodamage.We noticed that you're using an unsupported browser. I had ordered 2 small plates, some pasta and a glass of wine. The waiter took our order but didn't tell us the cost. When I looked at the menu, it only listed the cost of each plate and there was no total. The waiter checked...More We were surprised to find the service was quite good. The wait staff was professional, helpful and courteous. We were impressed.The food was good. It was not fancy but was very good. We shared a spinach crepe with prosciutto and brie. We are in our 40s...More My husband and I were very pleased with
